This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. Mortality Experience

OF THE

CONNECTICUT MUTUAL

Life Insurance Company,

OF

HARTFORD, CONN.,

From 1846 to 1878.

HARTFORD, CONN.,
1884.

CONNECTICUT MUTUAL LIFE INSURANCE COMPANY,

HARTFORD, August 31, 1883.

JACOB L. GREENE, *President*,

Dear Sir:

I submit herewith the results thus far deduced from the analysis of the mortality experience of this company. Some of these results are of very great interest and value. The facts are given in the tables submitted; the text is intended to call attention to the more important results, and as an explanation of the tables, rather than as a complete discussion of the facts.

You are already familiar with the general scope of the work. It was begun by your direction, and its general range has been determined in consultation with you. The clerical work has been done by those to whom it was intrusted cheerfully, carefully, and well. The value of the results obtained is an ample return for the care and labor involved in the undertaking.

Very respectfully,

D. H. WELLS, *Actuary.*

MORTALITY EXPERIENCE

OF THE

CONNECTICUT MUTUAL

LIFE INSURANCE COMPANY.

THE following results have been obtained by a careful analysis of the mortality experience of THE CONNECTICUT MUTUAL LIFE INSURANCE COMPANY from the commencement of its business to the year 1878: the observations being carried to the anniversaries of the issue of each policy in that year, or to their termination if prior.

A brief statement of the methods employed will be of service in making clear the exact bearing of the results obtained, and the degree of confidence to which they are entitled. It will also be of interest as indicating any variations from the methods more commonly used.

Cards were prepared giving the number, amount, kind, date of issue, date of expiry, mode of expiry, and duration of each policy, the name, sex, residence, occupation, place of birth, date of birth, and age when insured of the person insured thereby, and the numbers of any other policies on the same life. In case of joint life policies a card was filled out for each life. In case of policies which had been reduced or increased, the amount of the insurance was divided and treated as if it had been given under separate policies, which had been terminated or issued at different times. If a policy was changed in plan, as from life to endowment, or the reverse, it was treated as if surrendered and a new policy issued.

The data for the cards were obtained, so far as therein contained, from the original applications. The date and mode of expiry were obtained from the company's registers. The age when insured,

to the nearest year, was obtained by deducting the date of birth from the date of issue of the policy, and checked by comparison with the age as entered on the company's registers. The duration of the policy was obtained by a comparison of the dates of issue and expiry, if expired, and by subtracting the year of issue from 1878 if still in force. In case of policies which had expired by the death of the insured, any fraction of time in excess of whole years was counted as a year. In case of joint policies this was done only on the card representing the life deceased. In all other cases the duration was taken to the nearest year. In case of policies with premiums payable in fractional installments, which lapsed midway of the policy year, the half year was alternately added to and dropped from the duration. As the company, except in very rare instances, does not accept the surrender of a policy until after lapse, and as policy years were exclusively used and the observations on existing policies were carried to the anniversary of the policy, there were no other fractional parts of a year of any practical consequence to be provided for.

After the cards had been written, they were all carefully reviewed, both with the applications and registers. They were then classified, in the usual way, and the classes reviewed to guard against errors of classification. The cards of each class were then twice counted and the amount insured twice footed, and the results tabulated.

In order to obtain results by lives, both under different classes of policies and as a whole, all the cards were now grouped into six classes, the classification being by sex and kind, viz.:

1st. Premium-paying life and endowment policies, including policies paid up by term; 2d. Paid-up policies issued in lieu of policies surrendered; and 3d. Term policies.

The cards in each of these classes were then arranged by date of birth, and all those of the same date of birth carefully compared as to names. At the same time careful attention was given to the memoranda indicating other insurances on the same life.

If two or more cards were found in the same class representing policies upon the same life, if the policies were not connected in time

so as to make a continuous insurance, they were treated as if upon different lives; if they constituted a continuous insurance, the card was selected which carried the insurance to the latest date, and on this card were noted, in addition to the previous entries, the occupation as given on the other card or cards, the earliest date of entry and the corresponding age, and the duration, to the nearest year, of the entire continuous insurance. The cards so included in others were then thrown out.

The remaining cards representing policies of the three different classes upon lives of the same sex were next compared and combined in like manner, the additional entries being made in additional spaces. The cards thus included in others of a different class were then marked and replaced in their respective classes. In combining the cards representing policies of different classes, the insurance under a paid-up policy issued in lieu of a policy surrendered was treated as dating from the time the original policy ceased.

In thus comparing cards representing different policies on the same life, many cases were found in which the date of birth as stated in the different applications varied. If the life was still insured, inquiry was made by letter as to the correct date of birth, and the proper correction made. If no policy remained in force on the life, the date of birth as given in the application for the earliest policy was used in combining the cards.

The cards representing each class of policies were then distributed and the results tabulated. As always, the cards were carefully reviewed after being distributed in order to detect any error in distributing, and the tables were checked by a second counting of the cards. After these last results were tabulated, all cards marked as included in others were rejected, and the remaining cards representing policies on lives of the same sex were redistributed and the results tabulated without regard to class of policy.

The use of policy years instead of calendar years is believed to afford better facilities for the study of the question of selection, whether by the company at the inception of the contract, or by the insured in the after exercise of the option of continuing or discon-

tinuing it. It avoids also the disadvantage of dealing with a fraction of a year at the beginning of the observation, a fractional age at the beginning of the following calendar year, and a fraction of a year at the close of the discontinued insurances.

In the bringing together of cards representing insurance on the same life, the arrangement by dates of birth, instead of the usual alphabetical arrangement by names, was a great saving of labor, and it is believed contributed largely to accuracy; the indistinctness with which names are often written, and the unavoidable errors in copying such a number of them, together with changes, especially in names of females, making an alphabetical arrangement difficult and unsatisfactory. The addition of necessary changes on an existing card, instead of writing a new card or envelope, also saved much labor.

In the reduction of the observations, a series of checks was used which is believed to have rendered certain the detection of any error. A comparison of the results given in the accompanying tables shows a slight discrepancy between the table of male lives classified by occupation and the other tables of male lives. This discrepancy is due to some error in reclassifying the cards or recording the results by occupations, an error almost unavoidable in handling such a number of cards, and was so small that it was not considered worth while to attempt to correct it when discovered on footing and summarizing the tables. No other discrepancies are believed to exist, except such as arise inevitably from the use of a limited number of decimal places in the probable deaths and losses.

The analysis includes all policies issued prior to January 1, 1878, except 1420 small policies issued in lieu of cash dividends, which were omitted because they added no new lives, and being for small amounts would not have perceptibly varied the results by amounts.

As regards males, the observations included 97,790 lives, covering 780,353 years of exposure, with 8,746 deaths; 125,655 policies, covering 867,197 years of exposure, with 9,890 terminations by death; $354,902,195 of insurance, covering $2,482,744,335 of exposure, and a loss of $28,793,725 by death.

As regards females, there were included 7,452 lives, covering

62,680 years of insurance, with 756 deaths; 8,528 policies, covering 63,914 years of exposure, with 777 terminations by death; $17,575,404 of insurance, covering $131,962,559 of exposure, with a loss of $1,570,951 by death.

All cases in which anything was paid on account of a policy after the death of the insured, or in which suit was brought to enforce payment, are included among the deaths, and for the full amount of the policy.

Table I gives the observations on male lives in a form permitting of any desired combinations of ages or years of insurance.

Table II presents the same facts summed up (*a*) by groups of ages and of years of insurance, and (*b*) by years of insurance irrespective of age, with the addition of the probable deaths by the American Table and the ratio of the actual deaths to the probable deaths. We shall refer to this table again later.

Table III exhibits the mortality experience of the company as regards male lives, age by age, and gives, side by side with the actual deaths at each age, the probable deaths as determined by four of the most prominent mortality tables based upon insured lives: two American—the American Table and the Thirty American Offices' Table; and two English—the Combined Experience Table and the H^M. Table. A graphic representation of these tables and of the Company's experience, age by age, both as regards male and female lives, is given in Diagram I.

While this table exhibits at all the ordinary ages of insured life, say from 20 to 70, a very good degree of regularity in the death rate, the irregularities are sufficient to interfere seriously with any direct general comparisons, or the deduction of any exact general conclusions. In order to eliminate, in part, the irregularities which attach to the experience at individual ages, the results were combined in groups of five ages, and the results are given in Table IV. The ratio of the actual to the probable deaths by each of the four tables was also computed for each group of ages and added to the table. Inspection of the table shows that the mortality among the male lives insured by the company has been only 84.6 per cent. of that given by the American Table, 87.3 per cent. of that given by the Thirty

American Offices' Table, 77.8 per cent. of that given by the Combined Experience Table, and 80.0 per cent. of that given by the H^M. Table. Comparing the ratios for different groups of ages with the ratios of the totals, table by table, we find that the experience of the company runs more nearly parallel to the American Table than to either of the others; notably nearer than to the English Tables. Thus, the series of ratios obtained by comparing the actual mortality in these groups with the probable as given by the different tables, crosses the ratios of the totals by the same tables, in the case of the American Table, seven times; of the Thirty American Offices' Table, five times; of the Combined Experience Table and H^M. Table, twice each. Again, the arithmetical sum of the differences between the ratios of the totals and the ratios for the individual groups are in case of

	The American Table.	Thirty American Offices' Table.	Combined Experience Table.	H^M. Table.
For all ages, . .	1.226	1.540	1.550	2.301
Ages 26–90, . .	.555	.562	.586	.690
Ages 26–70, . .	.179	.294	.262	.421

The relation of the Company's experience, as given in Table IV, to each of these tables and also to the average (ratio of the total actual to the total tabular) mortality by each table is shown graphically in Diagram II. The tables are represented by the heavy horizontal lines taken as 100, and the average mortality by the parallel broken and dotted lines. The ratios of the actual to the tabular mortality by groups of ages are laid off on vertical lines, and the points so found connected by broken lines. The more nearly the broken lines so drawn approach towards coincidence with the broken and dotted lines, the more nearly the Company's experience approaches parallelism with the table.

The separate representations of the Company's experience as compared with each of the four tables, given in Diagram II, are superimposed and form Diagram III. The average mortality by each table successively was taken as 100, and the ratio of the actual to the tabular mortality by that table for each group of ages being increased in the same ratio, the

results were laid off as ordinates, and the points so found connected by distinctive broken lines. The nearer approach of the full broken line towards coincidence with the line representing the average mortality indicates the closer parallelism between the Company's experience and the American Table.

The published experience of the Mutual Life, and also of the Mutual Benefit Life, shows the same general result. Their mortality runs fairly parallel to the American Table, while the rate given by the English Tables is relatively much higher at the middle ages than at the extremes of the table. This seems to indicate a variation in the law of mortality as operating upon American and English insured lives.

The mortality of the group of ages 7–20, as shown by the table, is very heavy. The ratio of actual to expected for the following group, 21–25, is also greater than for any later group. This excessive mortality is partially accounted for by the mortality under term policies as exhibited in Table VII. If we deduct the actual and probable deaths under term policies, as given in Table VII, from the corresponding entries in Table IV, the ratio of actual to probable deaths by the American Table for ages 7–20 is reduced to 1.123, and for ages 21–25 to .859.

In addition to the causes operating upon term policies, which will be referred to later, there is a moral hazard in the insurance, under ordinary forms of policies, of lives which can, in general, have no present money value, in that there will naturally be a tendency to a selection against the company, which the most careful medical selection will scarcely wholly prevent. "Children's Endowment Policies," as issued by some companies, which provide only for the return of the premiums paid in case of death, avoid this hazard, but are not in any true sense life insurance policies, but only a method of accumulation.

The experience of the company, as regards male lives, runs so nearly paralled to the American Table, that for practical purposes comparisons with that table are preferable to comparisons with an adjusted table of the company's experience, and hence in all the fol-

lowing tables the American Table of Mortality has been taken as a standard of comparison.

Table XX gives the same facts, in part, as regards policies issued and amounts insured on male lives, as are given in Table IV regarding the lives. Comparing the two tables, we find the proportion of loss by policies to be slightly in excess of that by lives, and the loss by amounts to be somewhat larger still. The ratios of loss to exposure stand, for lives .01121; for policies .01141; for amounts .01157. In like manner the ratios of actual loss to the probable loss by the American Table stand, for lives .846; for policies .856; for amounts 879. Comparing the ratios of actual to probable loss by groups of ages, we find no very considerable variation between the ratios for lives and policies. The groups 7–20, 21–25, 41–45, and 86–90 give a slightly smaller ratio for policies than for lives; the remaining groups the reverse. The greatest differences are found in the groups 56–75, for which the average excess of the ratios for policies over the ratios for lives is .027.

The losses by amounts do not run so nearly parallel to the American Table as do the losses by lives and by policies. In this regard, as to amounts, there seems to be but very little choice between the four tables with which the losses by lives were compared.

Comparing the ratios of actual to probable loss for policies and amounts, we find the ratios for policies to be the greater for the first four groups, 7–35, notably so for the first two groups, 7–25, and the less for the following eight groups, 36–75. The excess of loss by amounts is especially noticeable for the ages 56–70, and is even more striking when we compare the losses by lives and amounts.

The ratios of loss to exposures for lives and for amounts are proportional to the ratios of the average amounts insured on the lives exposed and on the lives deceased. That is,

$$\frac{\text{Lives Deceased}}{\text{Lives Exposed}} \cdot \frac{\text{Amount Lost}}{\text{Amount Exposed}} \cdot \cdot \frac{\text{Amount Exposed}}{\text{Lives Exposed}} \cdot \frac{\text{Amount Lost.}}{\text{Lives Deceased.}}$$

The corresponding relation holds good as between lives and policies, and policies and amounts. The ratios of actual to probable loss are in the same proportion when only single ages are considered, or

groups of ages for which the same ratio of amounts to lives, policies to lives, or amounts to policies, as the case may be, holds for all the ages comprised in the group.

A comparison of the ratios of losses by lives and by amounts to the exposures, shows then at once that at certain ages an undue proportion of the deaths fell among those insured for smaller amounts, while at other ages the deaths fell largely among heavier insurers. For example, for ages 7–20 the average amount insured on each life exposed was $2,304.10, while on the lives deceased it was only $1,895.10; while for ages 66–70 the average amount insured on lives exposed was $2,827.67, while on lives deceased it was $3,248.65. That this could have been the result of a mere chance seems improbable when we consider the extent of the experience from which the results are deduced, and even more when we note the uniformity of the results age by age. Thus, comparing Tables III and XIX, we find that for ages under 30 the ratio of loss to exposure by lives exceeds that by amounts for sixteen ages, and is less for one age only; while for the fifteen ages, 56–70, the ratio of loss by amounts is in excess for fourteen ages, and less for only one age. A part of the difference at the early ages is due to the excessive death-rate under term policies, which were mostly for small amounts. The results at some other ages are affected by the losses under paid-up policies. If, however, we compare Tables V and XXI, which include only premium-paying life and endowment insurance, we shall still find considerable differences in the one direction for ages 7–25 and in the other direction for ages 56–75.

These results suggest the question whether those who insure for large amounts,—often, perhaps generally, men of good incomes and living well, but involved in the cares and burdened with the responsibilities of great business enterprises,—are more liable than other men to break down and die at about these latter ages.

Tables V, VI, and VII exhibit the mortality experience of the company as regards male lives insured under premium-paying life and endowment policies (including policies paid-up by term), paid-up policies issued in lieu of policies surrendered, and term policies, respectively

The deaths under premium-paying life and endowment policies were 84.4 per cent. of the expected deaths, the rate at the different ages running fairly parallel with the table. Compared with Table IV, the only striking variation is in the rate at ages 7–20 and 21–25, due to the exclusion of term policies as before pointed out. The results by policies and amounts, as given in Table XXI, do not differ materially, except as before noticed, from the results by lives.

Comparing the results as regards premium-paying life policies, Table XXII, with the results as regards premium-paying endowment policies, Table XXIII, we find a large difference in the ratios of actual to probable loss in favor of the endowments. As regards policies, the ratios are .870 and .607; as regards amounts, .893 and .635. This shows either a greater ability on the part of men apparently in good health and considered as desirable risks to estimate their own relative chances of life—a greater power of selection by the individual —than has generally been believed possible; or, otherwise, that those whose circumstances are such as to permit of the taking of endowment insurance have by far the best chance of long life.

The deaths under paid-up policies issued in lieu of policies surrendered were 80 per cent. of the expected deaths. The rate from 7–50 is 84.7 per cent., or slightly above that of premium-paying policies, as against 74 per cent. for the ages 51–85, indicating, perhaps, a more decided selection against the company at the older ages. The losses by policies and amounts, as given in Table XXIV, are 80.2 and 99.1 per cent. of the probable losses respectively. The loss by policies scarcely differs as a whole from the loss by lives. The greater loss by amounts, indicating that an undue proportion of the deaths fell among the holders of the larger paid-up policies, is probably due to the fact that the larger policies were more generally issued in lieu of limited premium life and endowment policies, and that, owing to the larger premiums, these policies were more often surrendered as a matter of necessity. Possibly the same cause may have contributed somewhat to produce the small ratio of loss under premium-paying endowment policies before noted.

The lower ratio of actual to probable deaths under paid-up poli-

cies as compared with premium-paying policies, indicates a selection against the company by the withdrawal of lives of more than average vitality; the greater ratio by amounts indicates an additional money loss due to the disproportional distribution of the deaths among large and small policies.

The ratio of actual to probable deaths among male lives insured under term policies, as shown by Table VII, is 1,745, or more than twice as great as among male lives insured under other forms of policies, or as a whole. This is due in great part to the fact that these policies were largely taken to cover special risks; especially on the lives of persons going to California to engage in gold-mining in 1849 and the years succeeding. The excessive mortality at the ages under 25, and especially under 20, is probably due to the immaturity of the lives and their consequent inability to endure the unusual strain put upon them. The same cause may also have operated to increase somewhat the mortality under premium-paying life and endowment policies, especially at the younger ages.

Table XXV exhibits the company's experience under term policies by policies and amounts. The ratio of actual to probable for amounts, 1.394, is considerably less than for lives and policies, but still very heavy, especially at the younger ages.

It does not follow from the high mortality experienced under term policies that the business resulted in a money loss to the company. The extra premium required for permits covering risks not covered by the policy contract, amounting in the year 1851 to over $38,000, and in the course of the company's business to over $500,000, a considerable share of which in the earlier years of the company's history was received from term policies, would probably more than offset the increased mortality. The table furnishes, however, a good illustration of the fact that there *are* special risks to be incurred under life insurance policies, and a warning against the folly of removing all restrictions upon such risks. Such risks, especially if temporary, always have sought and always will seek the cheapest insurance obtainable, and will gravitate to the company taking them at ordinary rates, rather than to a company charging a sufficient extra

premium; and quite possibly in sufficient numbers to cause serious loss. A careful analysis of the company's experience under policies involving special risks would have afforded very interesting and valuable results; but the labor involved was so great as to render such an investigation impracticable.

Turning now to the question of the effect of the duration of the insurance upon the mortality, Table II, including all male lives, and Table VIII, including only male lives insured under premium-paying life and endowment policies, tell essentially the same story. The ratio of actual to expected deaths for all ages for the five combined years of insurance, from the 6th to the 10th inclusive, exceeds the ratio of the subsequent years combined; and of these five years, the ratio for the 6th year of insurance is the greatest, it exceeding the ratio for each of the other years, except the 17th, 24th, 30th, 31st, and 32d. If we examine the groups of ages separately, we shall find that, in general, the ratios taken for groups of five years continue to increase to later years; the group 51–60 being an exception and having sufficient weight to determine the result in the summary of all ages. To elucidate this further the following table was prepared. It is deduced from Table II, including all male lives.

Ratio of actual to probable deaths by the American Table, for the years of insurance stated:

Ages at Death.	1-32	6-32	11-32	16-32	21-32	26-32
7-20	1.399	.493	.....	.....	.....	.....
21-30	.869	1.107	1.617	.....	.....	.....
31-40	.831	.914	1.010	.844	1.266	....
41-50	.841	.888	.925	.933	.908	.962
51-60	.863	.870	.806	.870	.796	.762
61-70	.837	.856	.878	.877	.899	.786
71-80	.813	.814	.822	.846	.901	.959
81-90	.....	.....	.785	.750	.727	.629
All	.846	.880	.868	.872	.862	.815

The column headed 1–32 shows the ratios of actual to probable deaths for the whole thirty-two years of insurance combined; the next gives the ratios obtained after excluding the first five years of insurance; the third after excluding the first ten years of insurance; etc. It will be noted that, taking all ages together, the highest ratio is obtained after excluding the first five years only, although this is not true of single groups of ages.

Tables XXVI and XXVII, which show the losses by policies and amounts under premium-paying life and premium-paying endowment policies respectively by years of insurance, exhibit no new facts deserving of special attention. Combining the two and reducing the results to the form of the table for lives given above we obtain the following tables, which are interesting for purposes of comparison.

Ratio of actual to probable number of premium-paying life and endowment policies ceased by death for the years of insurance stated:

Ages at Death.	1-32	6-32	11-32	16-32	21-32	26-32
7-20	1.146	.575	.....	.....	.....	.....
21-30	.822	1.199	1.732	.....	.....	.....

41-50	.834	.896	.919	.949	.943	1.014
51-60	.879	.905	.829	.881	.817	.807
61-70	.878	.908	.897	.908	.911	.779
71-80	.840	.842	.846	.861	.930	.942
81-90	.....	.....	.726	.692	.670	.624
All	.850	.909	.883	.889	.877	.817

Ratio of actual to probable losses by death under premium-paying life and endowment policies for the years of insurance stated:

Ages at Death.	1-32	6-32	11-32	16-32	21-32	26-32
7-20	1.069	.641	.....	.....	.....	.....
21-30	.812	1.288	2.077	.....	.....	.....
31-40	.847	.951	1.064	.706	1.550	.....
41-50	.852	.940	.964	1.052	.972	.928
51-60	.916	.941	.858	.955	.899	.848
61-70	.933	.987	.959	.973	1.012	.830
71-80	.833	.837	.853	.884	.976	1.014
81-90	.....	.....	.741	.716	.639	.649
All	.875	.951	.922	.954	.953	.868

Turning to Table IX, we find that in case of male lives insured under paid-up policies issued in lieu of policies surrendered, taken either as a whole or by groups of ages, (with a single exception,) the ratio of actual to probable deaths is greater for the first five years than for the remaining years. The single exception is the group of ages 51–60, for which the ratio for the first five years is .781 and for all years combined .783. The mortality as a whole is 80 per cent. of the probable mortality by the American Table, against a mortality of 84.4 per cent. in case of premium-paying policies, and decreases with the passing of each successive year of insurance until we reach the ninth year; the percentages obtained, first by including all years and then excluding successive years until we have excluded the first ten, being 80.0—79.4—78.9—78.0—72.2—70.9—64.1—54.8—53.6—60.2—27.4. The probable explanation of the greater mortality in the earlier years seems to be that while, as a whole, those who withdraw and take paid-up insurance are somewhat better lives than those who continue their insurance, a sufficient number of diseased lives also withdraw, from financial necessity or otherwise, to raise the mortality during the earlier years to nearly the average mortality under premium-paying policies: and that as these lives are weeded out

by death, the effect of the better lives becomes more and more apparent.

The ratios of actual to probable losses for policies and for amounts are also, as a whole, and, in general, for groups of ages, larger for the first five years of insurance than for the remaining years, as is shown by Table XXVIII. For all ages combined the ratios are:

Years of Insurance.	For Lives.	For Policies.	For Amounts.
1-5	.836	.833	1.018
6-10	.740	.741	.935
11-19	.274	.180	.074
All	.800	.802	.991

In Table X we note the heavy mortality under term policies at all ages and in all years of insurance, but particularly at the youngest ages and the first years of insurance. The ratio of actual to probable mortality for the ages 7–20 is 4.981 against 1.665 for the remaining ages, and 2.706 for the first year of insurance against 1.274 for the remaining years. The probable cause of this excessive mortality has been referred to. Like results are obtained for policies and for amounts, the losses by amounts being, however, less than by lives or policies, indicating that the losses fell heavily among the smaller policies.

Some of the most interesting and valuable results obtained in the course of the investigation are given in Tables XI and XII. Table XI exhibits the results obtained by classifying the male lives by the Country of their birth. Taking all ages together we find Natives to be the best risks, and the Irish the worst. Taking groups of ages there is great diversity. The most striking feature is the steady deterioration of the Germans with increasing age. From 21 to 70, by groups of ten ages, their record runs .636—.753—.973—1.237—1.283.

Table XII exhibits the mortality of male lives classified by occupation. The classification is not all that could be desired, principally owing to the indefiniteness with which the occupations were often given in the applications, especially in earlier years. Thus it would have been very desirable to subdivide class 19—Merchants—according to the nature of the business; but the application so generally gives the occupation merely as "Merchant" that such subdivision did not seem practicable. It is to be remembered, too, that the lives are selected lives, and the designation of the occupation will thus in some instances come to have a special or restricted meaning Thus, often when the designation is one that ordinarily is applied indiscriminately to employers and employed, or officers and subordinates, it may well happen that the lives under observation are almost exclusively of the former class. As instances we might name "Lumbermen," "Liverymen," "Teamsters," and "Mariners." Changes of occupation will also have had some effect on the results obtained, though probably not great. So far as it has effect it will have tended to equalize the observed death-rates. The number of lives under observation was also in some instances too small to entitle the results to credit.

The classes of occupation have been arranged in the order of the excellence of the risks as measured by comparison with the American Table. From this is excepted the last two classes, which are composed of lives of no particular occupation, but quite miscellaneous. The low mortality of the last class (49), and the great average duration of the insurances and the large per cent. still existing, are due to the introduction of a large percentage of the years of exposure without any corresponding deaths or withdrawals, at the expense of the other classes.

The same table exhibits the average duration of the insurances, and the proportion of lives still insured, in each class. The following tables give the classes which have exceeded the average, either in the duration of the insurances or the per cent. remaining insured, arranged in the order of duration and per cent. existing:

Class.	Average duration of Insurance.	Per cent. remaining Insured.	Class.	Per cent. remaining Insured.	Average duration of Insurance.
7	9.74	61	10	67	8.32
8	9.03	51	1	67	5.83
5	8.92	37	7	61	9.74
19	8.64	56	38	59	6.74
3	8.59	53	16	58	8.01
18	8.57	53	27	58	7.74
23	8.48	57	23	57	8.48
17	8.35	51	19	56	8.64
25	8.34	46	4	56	7.99
10	8.32	67	36	54	7.82
14	8.21	41	11	54	7.48
16	8.01	58	18	53	8.57
4	7.99	56	3	53	8.59
			24	52	7.35

Of the thirteen classes in the first group and the fourteen classes in the second group, eight classes are found in both. Eleven classes of the first group and nine classes of the second group, including seven of the eight common to the two groups, show a mortality below the average. The seven classes which show a duration and a per cent. of existing in excess of the average, and a mortality below the average, are 3, 4, 7, 10, 16, 18, and 19.

The comparison in Table XII has been made between the actual deaths and the probable deaths by the American Table. It will be remembered that the experience of the company does not run precisely parallel to the table, the most noticeable variation being an excessive mortality at ages under twenty-five, and especially under twenty. The deaths for ages 7–20 are distributed among the classes of occupations as follows, the probable deaths being also given for comparison:

Class	3	Actual	deaths	1	Probable	deaths	.05
"	14	"	"	2	"	"	.32
"	19	"	"	2	"	"	1.43
"	20	"	"	9	"	"	2.79
"	21	"	"	1	"	"	.72

Class	22	Actual deaths	2	Probable deaths	.75
"	27	" "	13	" "	11.71
"	43	" "	12	" "	9.12
"	44	" "	2	" "	.18
"	48	" "	7	" "	3.21

Class 49 has no actual against 1.22 probable deaths. In no other class do the probable deaths amount to 1, and only in two cases to .50. These figures indicate that the cause which produced the excessive mortality at these ages was not limited to any particular occupation or class of occupations. Classes 20, 22, 42, 43, and 45 also show a high rate of mortality for the ages 21–30, although in case of the three latter classes a high rate is not confined to these ages. Table XIII, giving the actual and probable deaths by groups of ages for each class of occupation, will permit of such further study of the subject as may be desirable.

The same table will well illustrate the fallacy involved in a comparison of the average age at death of persons of different occupations, as a measure of the healthfulness of the occupation. As an extreme illustration we will compare classes 35 and 43. Of class 35, 35 per cent. of the actual and 47 per cent. of the probable deaths fall in ages 61–90; while of class 43, 78 per cent. of the actual and 75 per cent. of the probable deaths fall in ages 7–30. The average age at death of class 35 is 56.8 years; while the average age at death of class 43 is 25.8 years; and yet the ratios of actual to probable deaths is for class 35, .979, and for class 43, 1.172, a difference in no wise corresponding with the difference in average age at death.

If we take two classes of occupations of more nearly similar character, 19 and 27, we find the ratio of probable deaths of 27 to probable deaths of 19 to be: for ages 7–30, 1.03; for ages 31–40, .38; for ages 41–50, .21; for ages 51–60, .15; for ages 61–90, .14; indicating by the rapidly-decreasing ratio a great difference in the average ages of the lives of the two classes. A corresponding difference in the average age at death would indicate only a similar healthfulness of occupation.

Table XIV gives the exposures, deaths, and ratio of deaths to exposures, of female risks, age by age. Table XV gives the same facts for groups of ages and of years of insurance, and also for groups of ages without regard to years of insurance,—the latter being a summary of Table XIV,—and adds to this the probable deaths by the American Table and the ratio of actual to probable deaths. Table XVI gives like facts in like form as regards female lives insured under premium-paying life and endowment policies. These last two tables give essentially the same results. We note that the death-rate is practically uniform for the groups of ages 7–50, and that for the groups 7–45 it is largely in excess both of the death-rate for male lives and of the table rate, while for the groups 46–80 it is below the rate for male lives as well as the table rate. The ratio of actual to probable for the totals of each table is .945.

The Thirty American Offices Experience shows an excess in the death-rate of females as compared with males between ages 15 and 45, the rate for ages 25–50 being substantially uniform, a lower rate for females than for males for the ages 46–65, and a higher rate again at the older ages. Comparing the H^M and the H^F Tables we find similar variations. The death-rate under the H^F Table is, in general, the greater for ages 20–47 and the less for the ages 48–83, and increases but slightly between 25 and 50.

Comparing Tables XXX and XXXI our attention is drawn to the larger ratio of loss under life policies as compared with that under endowment policies. This is in large part due to the fact that there were no exposures under endowment policies at ages beyond 65, and no losses at ages beyond 50. For younger ages we have the following ratios of loss to exposure for the two classes of policies:

Ages.	Life Policies.		Endowment Policies.	
	For Policies.	For Amounts.	For Policies.	For Amounts.
Under 36	.01057	.01004	.00995	.01047
36-50	.01089	.01066	.00433	.00377

The ratios of losses for the totals of the two tables combined is, for policies .01213 and for amounts .01182, while that for lives insured under the same policies is .01211. The losses by amounts were slightly less than by lives in case of females, while in case of males the reverse was true.

Tables XVII and XXXII exhibit the experience of the company on paid-up policies issued on female lives in lieu of policies surrendered. The ratios of losses to exposures were, for lives, .01173, for policies, .01194, for amounts, .01204. The ratio of loss to exposure for lives was greater for the first five years of insurance than for all years combined, notwithstanding the younger ages at exposure in the first five years. The ratio of actual to probable loss by the American Table was .941, or about the same as for premium-paying policies.

Tables XVIII and XXXIII exhibit the experience of the company on term policies on female lives. The ratios of losses to exposures were, for lives .01521, for policies .01705, and for amounts .02654. The losses by amounts were greater than by lives, while for male lives the reverse was true. The ratio of actual to probable losses by lives is 1.581.

Tables XXXIV and XXXV present the facts regarding the discontinuance of Premium-paying Life and Premium-paying Endowment Policies respectively, on male lives. The first fact which attracts attention is the rapid and regular decrease in the ratio of withdrawals as the age of the business increases. Of the $156,069,382 of premium-paying insurance lost otherwise than by the natural termination of the contract by death or expiry, $45,291,565, or 29 per cent., terminated after one year, $120,096,220, or 77 per cent., within the first five years, and $148,200,053, or 95 per cent., within the first ten years. These figures will be somewhat modified in the future, but they show very forcibly the fact that withdrawals are mostly confined to the earlier years of insurance. We note also that the loss is greatest in case of policies issued at the youngest ages, and decreases as the age at issue increases; also that the per cent. of withdrawals in case of endowment policies exceeds that in case of life policies, both as a whole and for each year of insurance, from the second to the thirteenth

inclusive. For the first year of insurance the withdrawals of life policies exceed. Beyond the thirteenth year of insurance there have been but very few endowment policies exposed, and only one withdrawal.

Tables XXXVI and XXXVII give the per cent. discontinued of Premium-paying Life and Endowment Policies, each kind being divided into three divisions by date of issue, viz.: those issued prior to 1865, from 1865 to 1869 inclusive, and from 1870 to 1877 inclusive. Comparing the tables we find that the loss of business by withdrawals increases with the later date of issue, and this not merely as a whole, which would be expected, but for the same years of insurance as well. A part of this increase is probably due to the greater competition for new business, resulting in the insuring of many who are unable or unwilling to continue the insurance, and in the inducements which are too often held out by unscrupulous solicitors to incite policy-holders in one company to exchange their policies for new ones in some other company. A large part of the increase of fifty per cent. in the discontinuances in the first year as between policies issued in 1846–1864 and those issued in 1870–1877, is to be thus accounted for. Another considerable cause is found in the doing away with the absolute forfeiture of lapsed policies, and the payment of equitable surrender values. The operation of this cause is abundantly illustrated in the increase of withdrawals at the end of the second year from two to eleven per cent., as between endowment policies issued in 1846–1864 and 1865–1869. Other causes are to be found in the distrust of life insurance caused by the failure of many speculative companies organized in the flush times following the war, and in the financial conditions of the times.
